

The EUSA Library Management System is a centralized web platform designed to streamline the loaning process of academic books and technical audiovisual equipment. This solution was developed to replace an inefficient legacy system. By implementing a robust multi-role architecture, the application allows students and administrative personnel to interact through a unified interface. Loan requests are processed dynamically, while active assets and returns are being monitored to ensure resource availability. Furthermore, automated sanctions are generated by the backend when deadlines are exceeded, and notifications are sent via email to keep users informed. The system is built using an Angular frontend and a Node.js-based API, which ensures high performance and scalability for the institutional infrastructure.
